

What Were the PCR Tests Based Upon ?

By July 2020 the CDC has stated that there were still no isolates of the Covid-19 virus.

- CASE NUMBERS: So what were the case numbers based upon ?
- BODIES : If people were dying from Covid-19, why weren't any virus samples available? Surely there were plenty of bodies to obtain a single sample from?
- If they could not obtain viral samples from anyone, then when they claim to have detected the virus in a person using the PCR, what were they really finding?

If no samples of the virus could be found in ANY of the bereaved, then what we have here is like a claim of murder without any trace of the murderer, and where the only "evidence" of the murderer is found elsewhere in a lab - where its origin was not from an infected person, but from a synthesis experiment !!.

It seems that they could not find any viral samples of COVID-19 in any of the millions of supposed infected or dead. So instead they used a synthetic piece of RNA in a lab ! According to the article below, the PCR test was based upon a piece of artificial RNA, not any RNA produced by a virus.
